

## **React Advanced Concepts – Online Learning Platform**

### **Introduction**

This project demonstrates the implementation of **advanced React concepts** by building an **Online Learning Platform**.

The main objective of the application is to improve **performance, reliability, and user experience** using real-world React patterns.

The following advanced concepts are implemented:

- Lazy Loading & Code Splitting
- Pure Components
- Error Boundaries
- React Portals

Each concept is implemented based on a user story and enhanced with bonus features for better demonstration and usability.

### **Challenge 1: Lazy Loading & Code Splitting**

#### **User Story**

As a user of an online learning platform, I want modules to load only when I click on them so that the application loads faster.

#### **Implementation**

Lazy loading is implemented using **React.lazy()** and **Suspense** to dynamically import the **CourseDetails** and **InstructorProfile** components.

These components are loaded only when the user interacts with the respective buttons, reducing the initial bundle size.

To clearly demonstrate the loading behavior during evaluation, an **artificial delay of 500 ms** is introduced while importing the components. This ensures the loading spinner is visible and easy to capture.

### **Code Snippet 1: Lazy loading with artificial delay**

```
const lazyWithDelay = (importFn, delay = 500) => {
  return lazy() =>
    Promise.all([
      importFn(),
      new Promise(resolve => setTimeout(resolve, delay))
    ]).then(([module]) => module)
  );
};

};
```

### **Code Snippet 2: Suspense with loader**

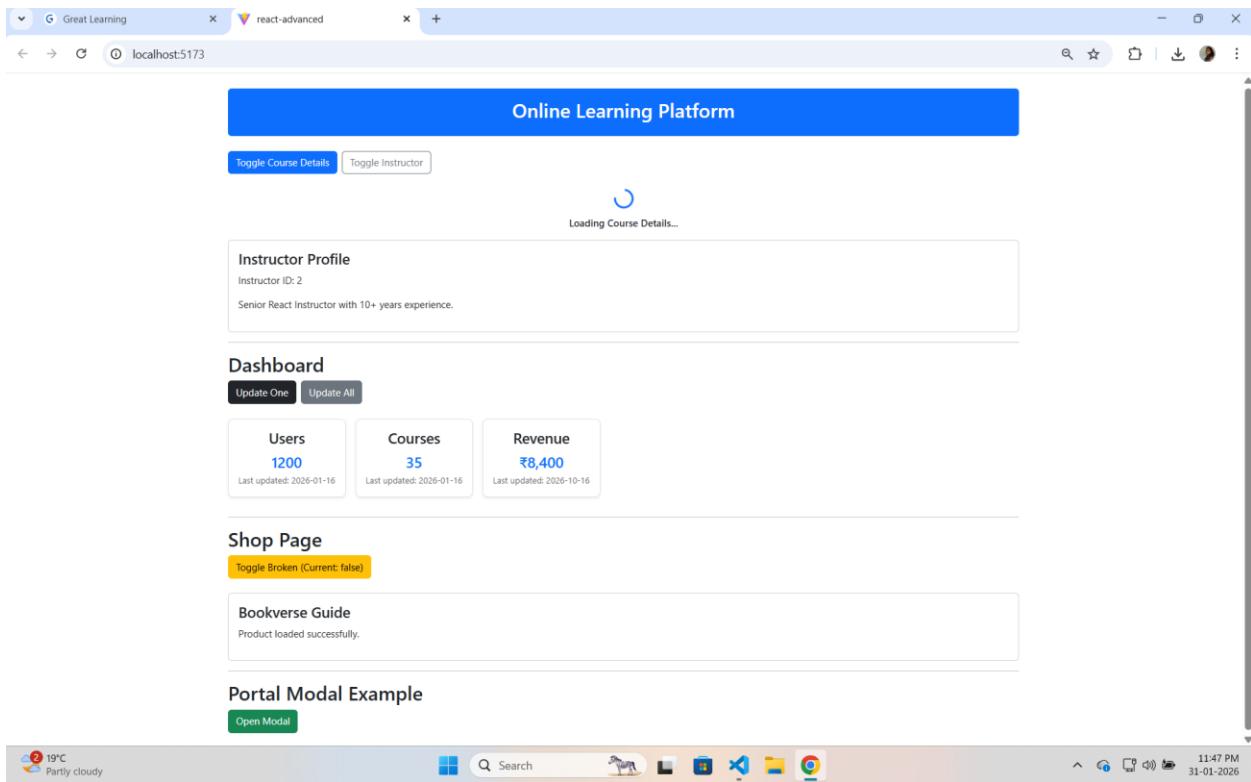

```
<Suspense fallback={<Loader message="Loading Course Details..." />}>
  <CourseDetails courseId={1} />
</Suspense>
```

### **Bonus Features Implemented**

- Bootstrap spinner during loading
- Context-specific loading messages
- Artificial delay for demonstration purposes

## Output Screenshot

Figure 1: Lazy loading with loading spinner

## Challenge 2: Pure Components

### User Story

As a dashboard viewer, I want widgets to re-render only when their data changes so that performance is optimized.

### Implementation

The **StatsCard** component is implemented as a pure component using **React.memo()**. This prevents unnecessary re-renders by performing a shallow comparison of props.

A **Dashboard** page displays multiple statistic cards and includes buttons to simulate updates.

Console logs are used to verify render behavior.

### Code Snippet: Pure Component using React.memo

```
const StatsCard = React.memo(function StatsCardInner({ title, value }) {
```

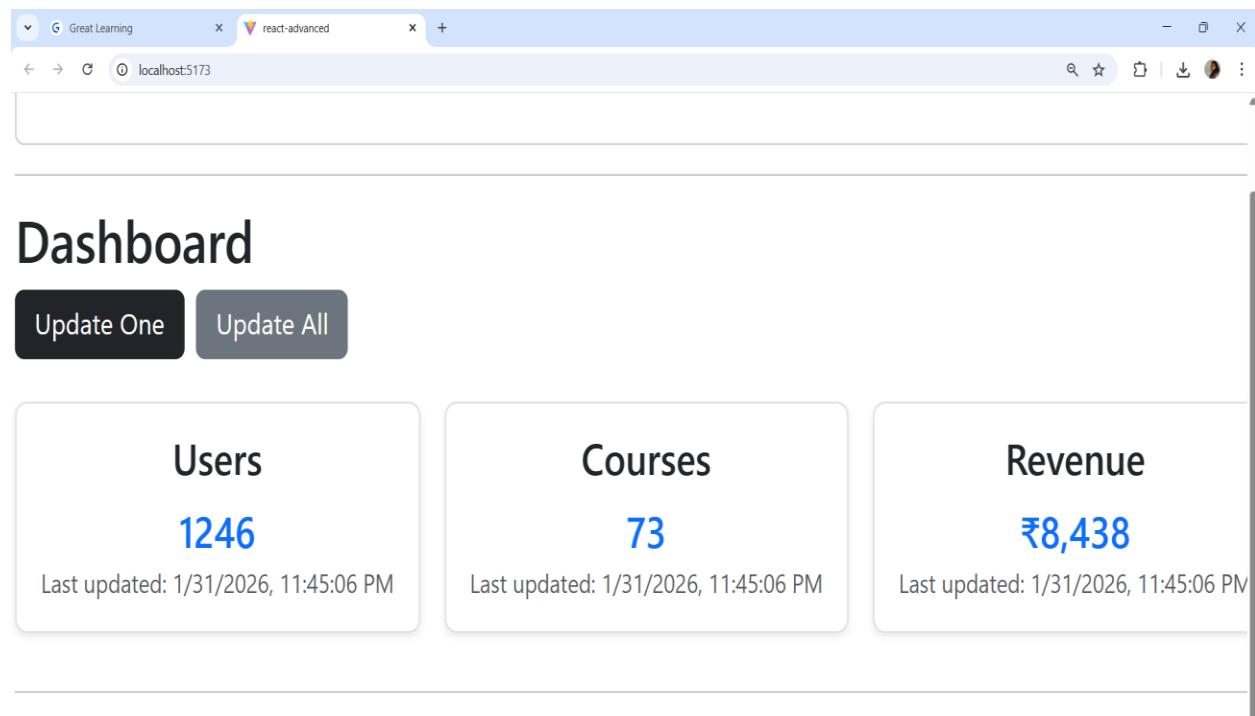

```
console.log(`Render: ${title}`);
return <div>{value}</div>;
});
```

### Bonus Features Implemented

- “Update One” button to update a single card
- “Update All” button to update all cards
- Console logging to observe optimization

### Output Screenshot

Figure 2: Dashboard demonstrating Pure Component behavior

## Challenge 3: Error Boundary

### User Story

As a product manager, I want the app to display a friendly error message instead of crashing when a component fails.

### Implementation

An **Error Boundary** is implemented as a class component using:

- `getDerivedStateFromError()`
- `componentDidCatch()`

A broken component (**BrokenProductCard**) is intentionally used to trigger a runtime error. The Error Boundary catches the error and displays a fallback UI without breaking the rest of the application.

### Code Snippet: Error Boundary lifecycle methods

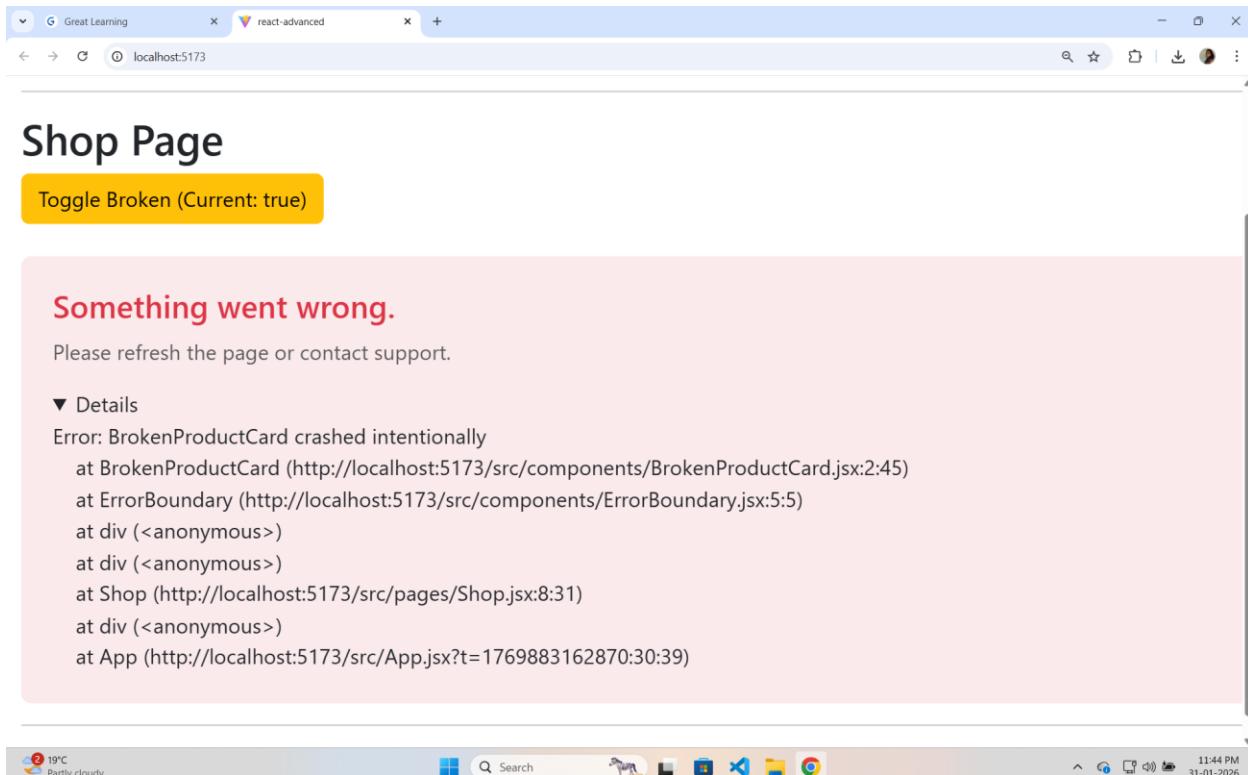

```
static getDerivedStateFromError(error) {  
  return { hasError: true };  
}  
  
componentDidCatch(error, info) {  
  console.error("Error caught:", error, info);  
}
```

### Bonus Features Implemented

- Error logging to the console
- Display of error details using `<details>`
- User-friendly fallback UI

## Output Screenshot

Figure 3: Error Boundary

## Challenge 4: React Portals

### User Story

As a user, I want notifications and modal popups to appear above all UI elements, even if nested inside components.

### Implementation

React Portals are used to render a modal into a separate DOM node (modal-root) outside the main React hierarchy using **ReactDOM.createPortal()**.

The modal supports:

- Open and close using state
- Backdrop click to close
- Escape key to close

## Code Snippet: Portal rendering

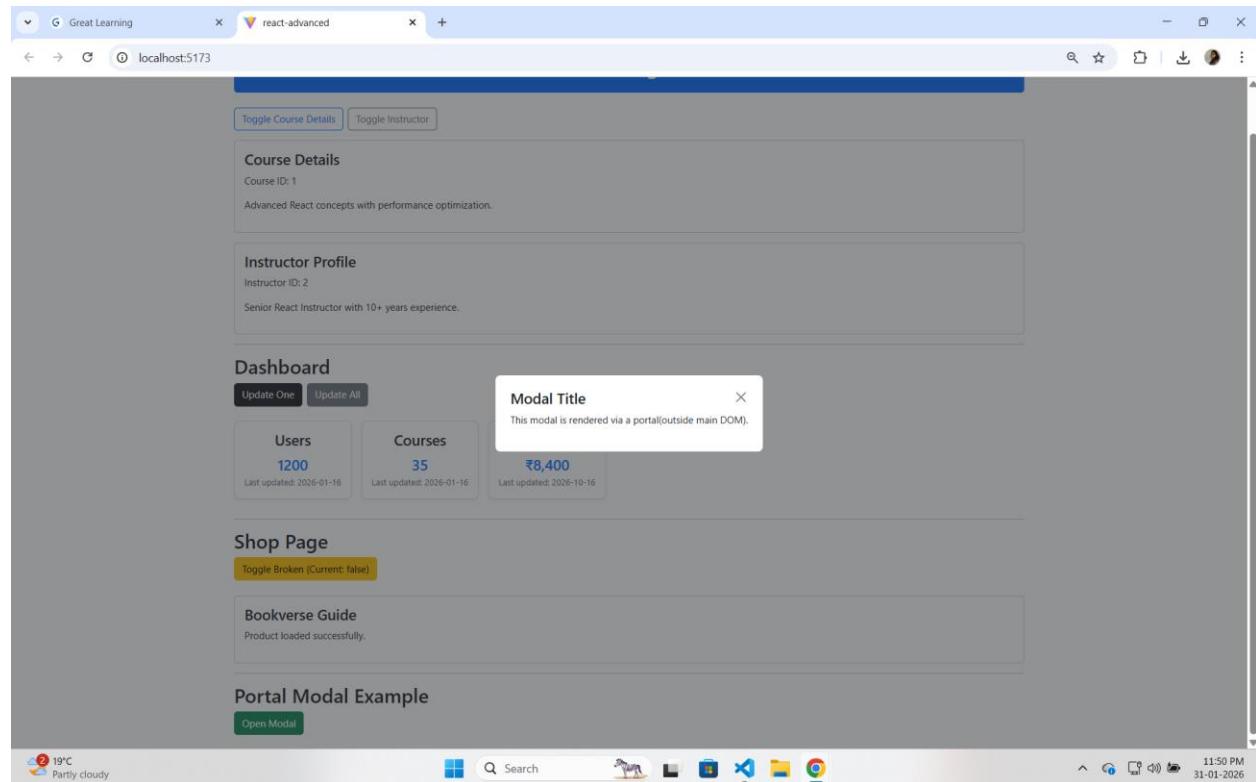

```
ReactDOM.createPortal(  
  <div className="modal-overlay">...</div>,  
  document.getElementById("modal-root")  
)
```

## Bonus Features Implemented

- Keyboard accessibility
- Clean overlay styling using Bootstrap

## Output Screenshot

Figure 4: Modal rendered using React Portal outside the main DOM hierarchy

## Complete Application View

This section shows the fully integrated Online Learning Platform containing all implemented features.

### Output Screenshot

**Figure 5: Complete Online Learning Platform showcasing all implemented features**

The screenshot displays the following sections of the Online Learning Platform:

- Course Details:** Course ID: 1. Description: Advanced React concepts with performance optimization.
- Instructor Profile:** Instructor ID: 2. Description: Senior React Instructor with 10+ years experience.
- Dashboard:** Includes "Update One" and "Update All" buttons. Statistics: Users (1200), Courses (35), Revenue (₹8,400). Last updated: 2026-01-16 for all metrics.
- Shop Page:** Shows a red error message: "Something went wrong." with the subtext "Please refresh the page or contact support." A yellow button labeled "Toggle Broken (Current: true)" is present. Below the message, there is a detailed error log:
  - ▼ Details
  - Error: BrokenProductCard crashed intentionally
  - at BrokenProductCard (http://localhost:5173/src/components/BrokenProductCard.jsx:2:45)
  - at ErrorBoundary (http://localhost:5173/src/components/ErrorBoundary.jsx:5:5)
  - at div (<anonymous>)
  - at div (<anonymous>)
  - at Shop (http://localhost:5173/src/pages/Shop.jsx:8:31)
  - at div (<anonymous>)
  - at App (http://localhost:5173/src/App.jsx?t=1769883778213:30:39)
- Portal Modal Example:** A green "Open Modal" button.

## Conclusion

This project successfully demonstrates advanced React concepts used in real-world applications. By implementing lazy loading, pure components, error boundaries, and portals, the application achieves:

- Improved performance
- Enhanced reliability
- Better user experience
